

# Statistical inference and linear models

February 20, 2018

# If you get bored

- Go to the last slide for bonus exercises
- Work on code for your research and ask question during exercise time
- But try and keep an eye out, just in case

# Disclaimer

- Assume you got lectures about statistics and
  - ▶ know why we need statistics
  - ▶ have heard of the general philosophy
- We may simplify to focus on practical aspects
- Correct us if we say something completely awful

- 1 Statistical inference
- 2 t-test, ANOVA, regression: all is one, one is all
- 3 Linear models in details
- 4 Bonus fun

# General approach

## 1. Scientific question

# General approach

1. Scientific question

2. Model and Statistical question

# General approach

# General approach

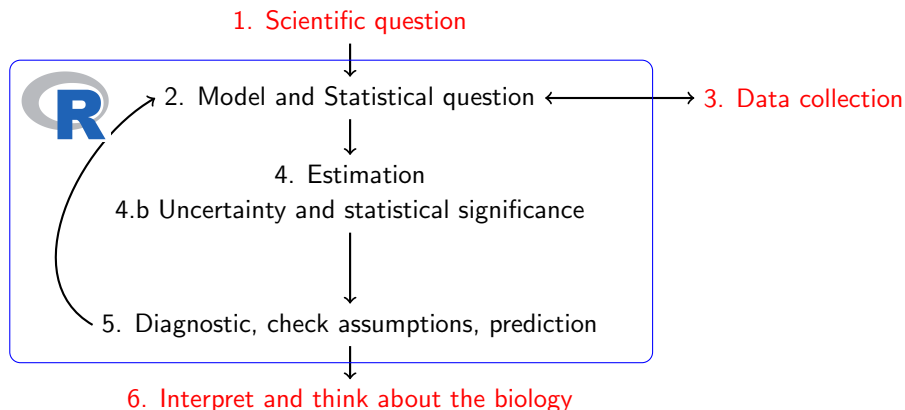

# General approach

# General approach

# Reminder t.test

# Reminder t.test

```
data("iris")
```

```
str(iris)  
plot(iris)
```

- 1 Scientific question: Are the taxa "setosa" and "versicolor" different species?

# Reminder t.test

```
data("iris")
```

```
str(iris)  
plot(iris)
```

- ① Scientific question: Are the taxa "setosa" and "versicolor" different species?
- ② Model and stat question:
  - ▶ Model:
    - ★ There is an intrinsic/expected sepal length value for a species; an individual value is the sum of this expectation and a random Gaussian deviation.
    - ★  $y_i = \mu_{species_i} + \epsilon_i$  with  $\epsilon \sim N(0, \sigma^2)$
    - ★ t-test

# Reminder t.test

```
data("iris")
```

```
str(iris)  
plot(iris)
```

① Scientific question: Are the taxa "setosa" and "versicolor" different species?

② Model and stat question:

► Model:

- ★ There is an intrinsic/expected sepal length value for a species; an individual value is the sum of this expectation and a random Gaussian deviation.
- ★  $y_i = \mu_{species_i} + \epsilon_i$  with  $\epsilon \sim N(0, \sigma^2)$
- ★ t-test

► Statistical question:

- ★ Does sepal length **differ significantly** between the two taxa **in our sample**?
- ★ Is the observed difference between taxa likely if both taxa have the same intrinsic/expected value?

③ Data collection

# Reminder t.test

One t-test for sepal length between *setosa* and *versicolor*:

```
t.test(x = iris$Sepal.Length[iris$Species == "setosa"],  
       y = iris$Sepal.Length[iris$Species == "versicolor"])
```

Welch Two Sample t-test

```
data:  iris$Sepal.Length[iris$Species == "setosa"] and iris$Sepal.Length[iris$Species == "versicolor"]  
t = -10.521, df = 86.538, p-value < 2.2e-16  
alternative hypothesis: true difference in means is not equal to 0  
95 percent confidence interval:  
 -1.1057074 -0.7542926  
sample estimates:  
mean of x mean of y  
   5.006    5.936
```

# When do we know it is different?

## ④ Statistical estimation

### ► a Estimation

- ★ Cannot know true difference  $\mu_{species_1} - \mu_{species_2}$
- ★ Estimated difference = **Mean<sub>1</sub> - Mean<sub>2</sub>**
- ★ Difference contains random variation

### ► b Quantify uncertainty / Statistical significance

- ★  $t = \frac{\text{Mean}_1 - \text{Mean}_2}{\text{Variation}} \frac{\sqrt{\text{Sample Size}}}{\sqrt{2}}$
- ★ We know exactly how  $t$  is distributed when  $\mu_{species_1} - \mu_{species_2} = 0$
- ★ Hence we know probability of  $\geq t$  if  $\mu_{species_1} - \mu_{species_2} = 0$  ( $p$ -value)
- ★ Can derive confidence interval and standard error

# When do we know it is different?

## • Statistical estimation

### ▶ a Estimation

- ★ Cannot know true difference  $\mu_{species_1} - \mu_{species_2}$
- ★ Estimated difference = **Mean<sub>1</sub> - Mean<sub>2</sub>**
- ★ Difference contains random variation

### ▶ b Quantify uncertainty / Statistical significance

- ★  $t = \frac{\text{Mean}_1 - \text{Mean}_2}{\text{Variation}} \frac{\sqrt{\text{Sample Size}}}{\sqrt{2}}$
- ★ We know exactly how  $t$  is distributed when  $\mu_{species_1} - \mu_{species_2} = 0$
- ★ Hence we know probability of  $\geq t$  if  $\mu_{species_1} - \mu_{species_2} = 0$  ( $p$ -value)
- ★ Can derive confidence interval and standard error

Less uncertainty with

- **Larger absolute difference**
- **Smaller variability**
- **Larger sample size**

# When do we know it is different? Simulations

# When do we know it is different? Simulations

## 1. Larger absolute difference

```
nbsim <- 1000
pdistri_large <- vector(length = nbsim)
pdistri_small <- vector(length = nbsim)
for (i in 1:nbsim)
{
  x1 <- rnorm(n = 10, mean = 2, sd = 1)
  x2 <- rnorm(n = 10, mean = 4, sd = 1) #large diff
  x3 <- rnorm(n = 10, mean = 2.5, sd = 1) #small diff
  out_large <- t.test(x1, x2)
  out_small <- t.test(x1, x3)
  pdistri_large[i] <- out_large$p.value
  pdistri_small[i] <- out_small$p.value
}
```

# When do we know it is different?

```
par(mfrow=c(1,2), cex=2)
hist(pdistrib_large, xlim=c(0,1),
     main=paste("Prop signif=",mean(pdistrib_large<0.05)))
hist(pdistrib_small, xlim=c(0,1),
     main=paste("Prop signif=",mean(pdistrib_small<0.05)))
```

**Prop signif= 0.989**

**Prop signif= 0.193**

```
par(mfrow=c(1,1))
```

# When do we know it is different? Try it!

## Exercise

Check the effect of **smaller variability** and/or **larger sample size**.

## By the way, what are these p-values?

*Probability for a summary statistic to be greater or equal to the observed summary statistic, **when the null-hypothesis of a given statistical model is true.***

# By the way, what are these p-values?

*Probability for a summary statistic to be greater or equal to the observed summary statistic, **when the null-hypothesis of a given statistical model is true.***

## Properties

- Depends on the null-hypothesis ( $H_0$ ) of a given model with assumptions
- Uniform distribution under  $H_0$  ...
- ... hence  $\text{proportion}(\text{significance under } H_0) = \text{significance threshold}$

# By the way, what are these p-values?

*Probability for a summary statistic to be greater or equal to the observed summary statistic, **when the null-hypothesis of a given statistical model is true.***

## Properties

- Depends on the null-hypothesis ( $H_0$ ) of a given model with assumptions
- Uniform distribution under  $H_0$  ...
- ... hence  $\text{proportion}(\text{significance under } H_0) = \text{significance threshold}$

**NB: Focus on  $p$ -value criticized, but common and they not more evil than other misused statistics!**

# T-test exercise: p-values and simulations

```
t.test(x = ..., y=..., var.equal = TRUE)
t.test(x = ..., y=..., var.equal = FALSE)
```

What if variance are different by chance only?

```
set.seed(1234)
var(rnorm(20, mean = 0, sd = 1))
```

```
[1] 1.027806
```

```
var(rnorm(20, mean = 0, sd = 1))
```

```
[1] 0.6265501
```

## Exercise

What option is more correct for var.equal?

- 1 Statistical inference
- 2 t-test, ANOVA, regression: all is one, one is all
- 3 Linear models in details
- 4 Bonus fun

# A small example

Animal behavior in response to weather

Load data:

```
getwd()  
setwd()
```

```
Error in setwd(dir =  
"Documents/GitHub/Rcode-Stats-Bubbles/3.linear_models/"): cannot  
change working directory
```

```
dat.behav <- read.csv(file = "datbehav.csv") # path to file
```

# A small example

Animal behavior in response to weather

Load data:

```
getwd()  
setwd()
```

```
Error in setwd(dir =  
"Documents/GitHub/Rcode-Stats-Bubbles/3.linear_models/"): cannot  
change working directory
```

```
dat.behav <- read.csv(file = "datbehav.csv") # path to file
```

STEP 1: have a look at your data

```
str(dat.behav)  
summary(dat.behav)  
plot(dat.behav)
```

# t-test

```
fitstudent <- t.test(x = dat.behav$activity[dat.behav$weather=="rainy"],  
                    y = dat.behav$activity[dat.behav$weather=="sunny"],  
                    var.equal = TRUE)  
print(fitstudent)
```

## Two Sample t-test

```
data: dat.behav$activity[dat.behav$weather == "rainy"] and dat.behav$activity[dat.behav$weather == "sunny"]  
t = 3.2752, df = 33, p-value = 0.002485  
alternative hypothesis: true difference in means is not equal to 0  
95 percent confidence interval:  
 0.6138373 2.6270325  
sample estimates:  
mean of x mean of y  
6.781476 5.161041
```

# t-test, graphically

## Difference between means

# ANOVA

```
fitanova <- aov(data = dat.behav, formula = activity ~ weather)
summary(fitanova)
```

|           | Df | Sum Sq | Mean Sq | F value | Pr(>F)     |
|-----------|----|--------|---------|---------|------------|
| weather   | 1  | 11.25  | 11.253  | 10.73   | 0.00248 ** |
| Residuals | 33 | 34.62  | 1.049   |         |            |

---

Signif. codes: 0 '\*\*\*' 0.001 '\*\*' 0.01 '\*' 0.05 '.' 0.1 ' ' 1

# ANOVA, graphically

## Variance decomposition

# Linear regression

```
fitlm <- lm(data = dat.behav, formula = activity ~ weather)
summary(fitlm)
```

Call:

```
lm(formula = activity ~ weather, data = dat.behav)
```

Residuals:

|  | Min     | 1Q      | Median | 3Q     | Max    |
|--|---------|---------|--------|--------|--------|
|  | -2.3547 | -0.6028 | 0.2346 | 0.6419 | 1.6534 |

Coefficients:

|              | Estimate | Std. Error | t value | Pr(> t )     |
|--------------|----------|------------|---------|--------------|
| (Intercept)  | 6.7815   | 0.4581     | 14.805  | 3.94e-16 *** |
| weathersunny | -1.6204  | 0.4948     | -3.275  | 0.00248 **   |

---

Signif. codes: 0 '\*\*\*' 0.001 '\*\*' 0.01 '\*' 0.05 '.' 0.1 ' ' 1

Residual standard error: 1.024 on 33 degrees of freedom

# Regression, graphically

## Rate of change

## NB: aov() vs. anova()

```
aov(data = dat.behav, formula = activity ~ weather)
anova(fitlm)
```

# All is one. . .

# All is one. . .

...but `lm()` rules!

- t-test, ANOVA, regression and others can be mathematically equivalent
- In R, `lm()` and related functions can do them all. . .
- ...and much more!
